ISZE · UNITS IN OPERATION · DECISION PACK

The car park is sound. The forecast is not.

History 1990–2025 is usable and should keep being used. The **2026–2030 forecast must not be quoted** until one defect is repaired: the forecast columns scrap only **3% of the fleet a year**, implying a 33-year vehicle life, while the survival curves that build the history imply 8 to 10. Real registration volumes are now added on top of that unchanged placeholder — which is what turns **falling registrations into growing fleets**.

This is not a modelling detail. Every GPS target wallet, every parts € per truck, every capture denominator and every Extended Target divides by fleet size — and so inherits the error.

The Ireland and Portugal registration upgrades delivered in June were **good work** and made the numbers more honest. They are being blamed for a forecast-method change made the same week. Those are two different stories and leadership should stop hearing them as one.

LOCKED FOR FY27 GPS & EXTENDED TARGET

44,926

IUK LCV CY2026 forecast — **−6.0%** against 2025E of 47,783.
The current file says 49,280 (+3.1%). That figure must not leave the building.

Prepared for OEM · Distributor · ISZE management

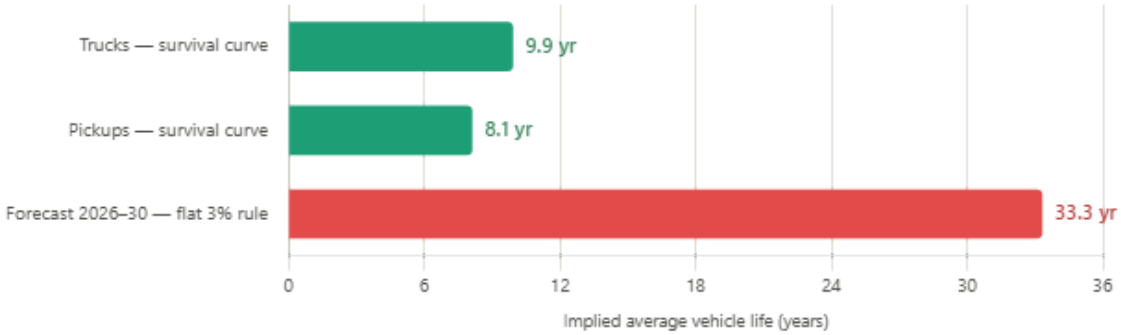

30 July 2026 · supersedes V19 forecast layer

01 What actually broke

The model is a simple loop: take last year's fleet, remove what was scrapped, add what was newly registered. For **1990–2025** the removal step uses a survival curve — a table of how many vehicles of each age are still on the road. **The forecast columns have never used it.** They remove a flat 3% per year: a placeholder inherited from a time when those rows carried no registration input at all.

While those rows were pure decay they simply declined, and the placeholder did no visible damage. That changed on **11 June 2026**, when the forecast was deliberately upgraded to add real registration volumes from the IMIT study and the mid-term sales plan. **That addition was correct.** What was never done alongside it was replacing the 3% placeholder with the survival curve. Registrations now flow in at full strength against a scrap rate three times too low — so the fleets grow.

The two halves of the file therefore disagree profoundly. A 3% annual scrap rate implies the average vehicle stays on the road for **33 years**. The survival curves in the very same file imply **9.9 years** for trucks and **8.1 years** for pickups. On 1 January 2026 the vehicles in our model begin living three times longer than they did on 31 December 2025. Nothing changed in the real world — only the arithmetic.

Implied average vehicle life by method. The first two bars are what the file uses for history; the third is what it switches to for the forecast.

FORECAST CELLS TESTED
195 / 195
every one fits
fleet × 0.97 + registrations

SCRAP RATE APPLIED 2026–30
3.0%
33.3-year vehicle life

SCRAP RATE THE CURVES IMPLY
10–12%
9.9 yr trucks · 8.1 yr pickups

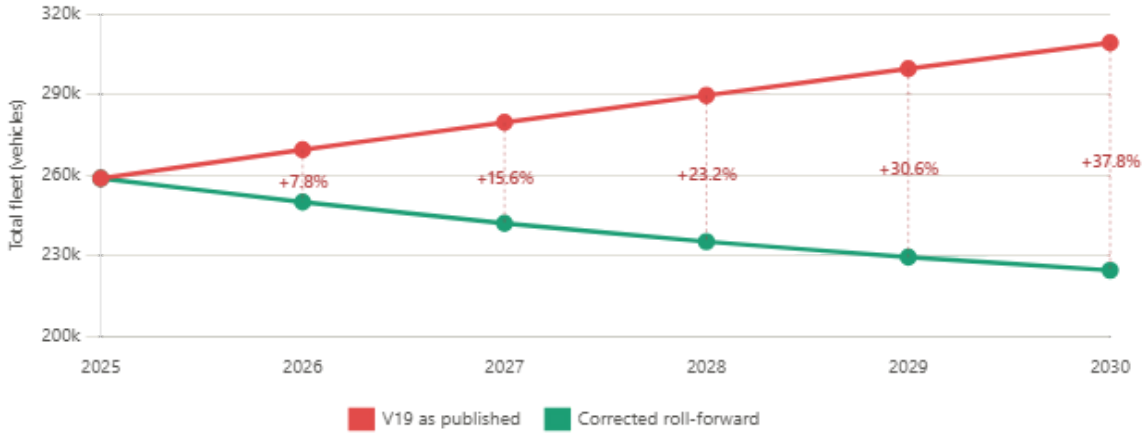

MEASURED IN THE FIELD
7.6–13.3%
Ireland & Portugal, from shipment records

This is verified, not alleged. Every one of the 195 forecast cells in the file reproduces exactly as *previous year × 0.97 + registrations*. The rule is not an approximation of something more sophisticated — it is the whole method. Two independent field measurements, Ireland at 13.3% and Portugal at 7.6% per year, bracket the curve and land nowhere near 3%.

And it is fully auditable. The change is documented in the file's own changelog as entries **V18-16 and V18-17, dated 11 June 2026**, which record the addition of registration inputs while retaining the 0.97 decay. The consequence was logged at the same time, in entry V18-18: *"Grand total now shows market growth instead of decline."* Nothing here was hidden — it was recorded as an improvement rather than recognised as a defect.

02 How big it is — and where

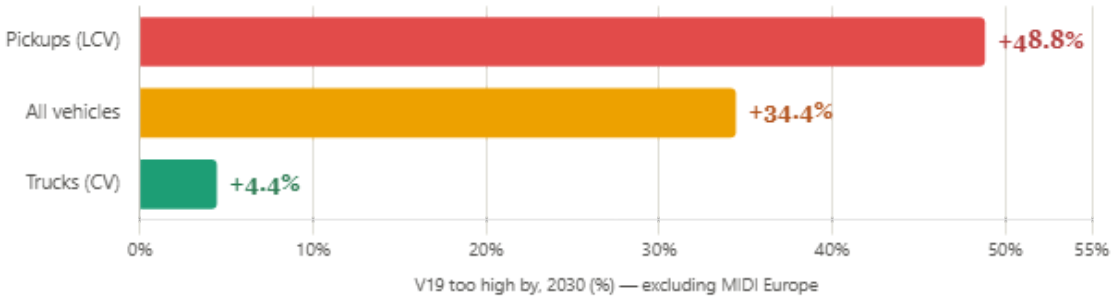

Rolling the file forward on the correct scrap assumption instead of the flat rule shows the overstatement compounding every year: **7.8% too high in 2026, 37.8% by 2030**. Because the error is multiplicative, it does not stabilise — it keeps widening after 2030.

Total fleet across all rows. V19 as published against the same file rolled forward on the survival assumption already used for history.

The error is almost entirely in pickups — the truck forecast largely survives

This is the single most useful thing in this pack, and it is not obvious from the totals. Splitting the overstatement by segment shows the commercial-vehicle forecast is only **4.4%** high by 2030, which is tolerable. The pickup forecast is **48.8%** high. The emergency is narrow and specific.

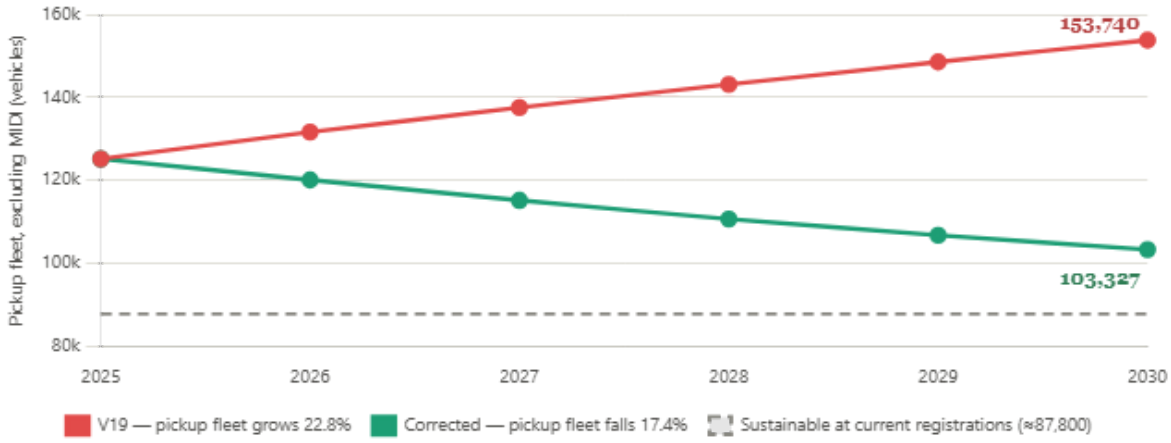

Overstatement by 2030, excluding MIDI Europe. Trucks are broadly defensible; pickups are not.

> **What this buys leadership.** The truck (CV) forecast can keep being used for planning conversations with a stated caveat. The pickup rows cannot be used at all until repaired. That is a far more workable message than "the whole forecast is wrong", and it is what the data supports.

Pickups do not just come down in magnitude — they reverse direction

IMIT's November 2025 study has ISZE pickup registrations falling from 16,977 in 2024 to 10,845 in 2026, a drop of **29%**. Every one of those inputs is correctly entered in the file. Yet the model still has the pickup fleet **growing 22.8%** between 2025 and 2030. Both cannot be true.

The cleanest way to see it: at 10,845 registrations a year and an 8.1-year life, the fleet can only support about **88,000** pickups. We already carry **125,168**. The fleet is 42% larger than the current registration rate can hold up. It must fall, and on the corrected assumption it does — to around 103,000 by 2030.

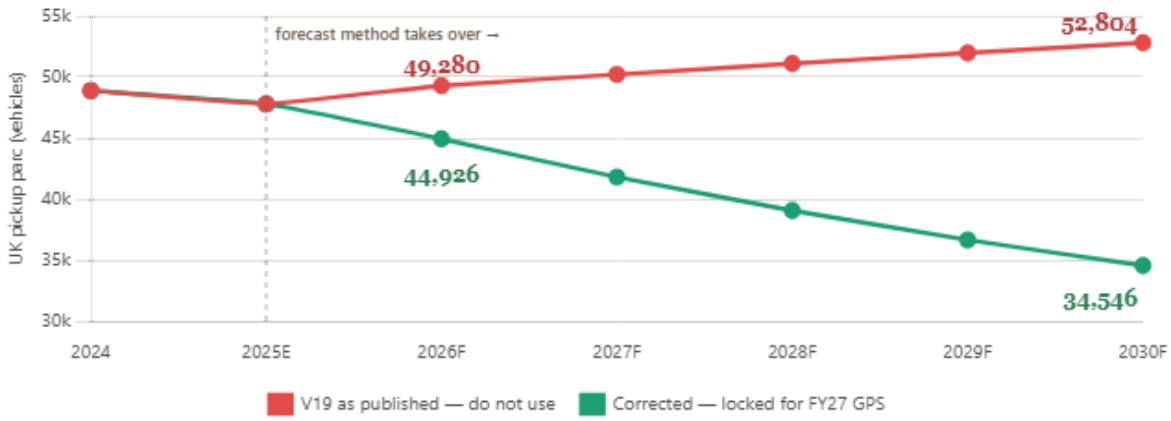

Pickup fleet excluding MIDI Europe. The dashed line is the level that current registrations can sustain over an 8.1-year life.

03 The number to take away: IUK LCV

One figure in this file has an immediate commercial consequence, because FY27 GPS and the Extended Target both need a CY2026 UK pickup parc. That number is **44,926**, not 49,280.

The UK D-Max registration collapse is not in dispute: IMIT has 7,013 in 2024 falling to roughly 3,020 in 2026, down 39% in a single year, under ZEV-mandate and benefit-in-kind pressure with the order strip still entirely combustion. Yet V19 has the UK pickup parc *rising* from 47,783 to 49,280 and climbing to 52,804 by 2030 — purely because of the 3% rule.

UK pickup parc. 2024 and 2025E are actuals and unchanged; the paths separate only where the forecast method takes over.

IUK LCV PARC	2024	2025E	2026F	2030F	STATUS
V19 as published	48,876	47,783	49,280	52,804	Do not use
Corrected (locked)	48,876	47,783	44,926	34,546	Use for FY27 GPS
Change 2025E → 2026F	—	—	**−6.0%** vs +3.1%	—	9.1 pt swing

Arithmetic, in one line. 47,783 × (1 − 0.123) + 3,020 = **44,926**. The 2025E level of 47,783 is retained deliberately — the 2024→2025 decline of −2.2% is already correct and IMIT-aligned. Only the forecast step changes. GPS Extended Target must replace its +3.13% UIO growth assumption with **−6.0%**.

04 Why we are confident: three independent proofs

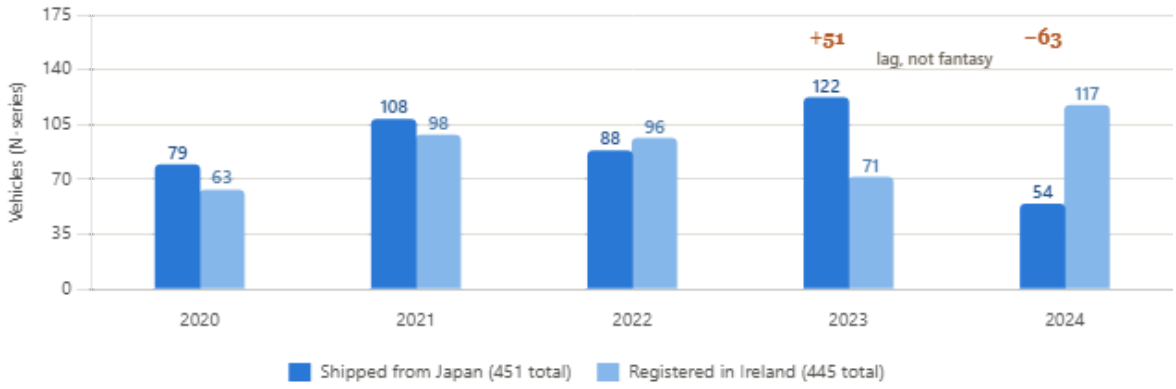

Proof 1 — the engine is understood exactly

Ireland's fleet was rebuilt from scratch using the registration history already in the file and the survival curve. The rebuild returned **731** trucks for 2025. The file says **731**. An exact match means the disagreement is not about how the model works — it is only about the forecast step. Run that same engine forward and Ireland's 2030 truck parc is 19–26% lower than V19, pickups 26–34% lower.

The steady state makes it unmistakable. If Ireland registers 216 trucks a year indefinitely, the fleet settles at 216 × 9.9 = about **2,138**. Under the 3% rule it settles at **7,200** — more than three times higher, from identical inputs. The 2030 figure is only where the error has reached by then.

Proof 2 — the sales plan does match reality, at the level

A new shipment register of **3,238** individually identified vehicles built and shipped from Japan 2020–mid-2026 lets us test, for the first time, whether planned volumes actually reach the road. For Ireland, where both shipment and government registration records exist, five-year shipments of **451** compare against **445** registrations — a difference of **1.3%**.

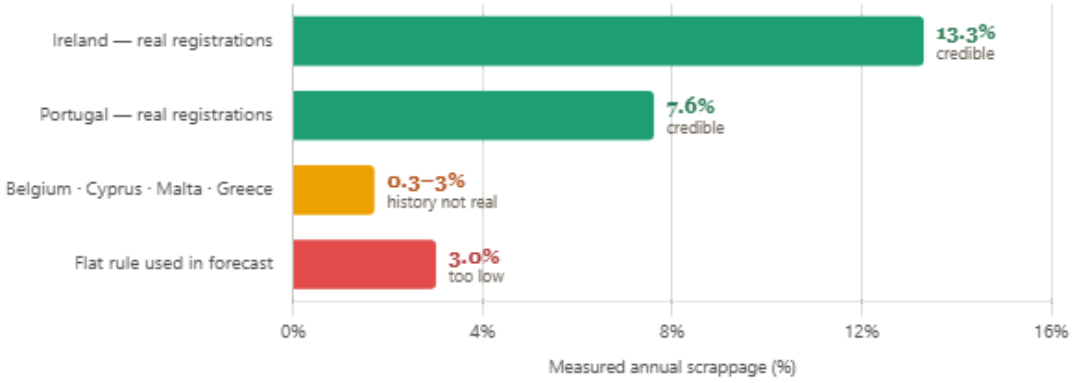

Ireland, N-series only on both sides. Individual years swing by 50–70 units in both directions; the five-year totals converge.

> **Two conclusions, and they are different.** Using the plan one-to-one *on the level* is now evidence-backed — that decision stands. Using it one-to-one *year by year* is not: 2023 ran 51 units ahead and 2024 ran 63 behind, because vehicles shipped in one year register in the next. The annual profile needs smoothing or an explicit shipment-to-registration lag, or single forecast years will be visibly wrong even when the five-year total is right.

Proof 3 — measured scrappage, from shipments rather than assumption

Where fleet history rests on real registration data, actual scrappage can be measured directly: Ireland **13.3%** per year, Portugal **7.6%**. Both bracket the survival curve. Neither is close to 3%.

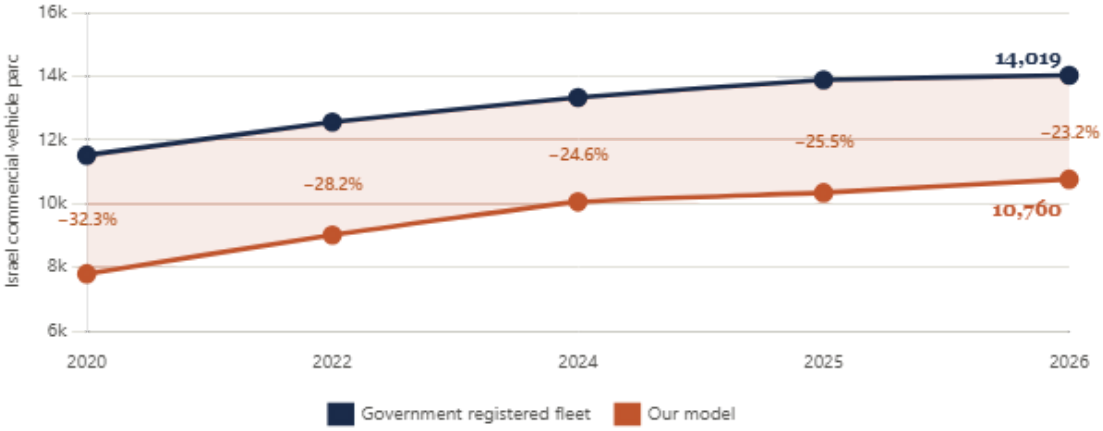

Running the same calculation on Belgium, Cyprus, Malta and Greece returns 0.3–3% per year. That is not evidence those markets scrap less — it is evidence their fleet history was never built on registration data in the first place, and it only became visible once the shipment register existed.

Measured annual scrappage. Green markets have registration-based history and are credible. Amber markets return implausible rates, which flags the history rather than the scrappage.

05 Israel: a missing block, not a scrap tweak

Israel sits about a quarter low in **every single year**. The gap holds at roughly 3,300–3,700 vehicles across seven years. A gap that steady means a **block of vehicles is missing from the mapping** — not that a decay rate is slightly off.

Israel commercial-vehicle parc. Government figures are Ministry of Transport registrations, the same class of source as SIMI in Ireland and stronger than the shipment file currently used.

At 30 June 2026 the government total of 14,019 breaks into four weight classes that sum exactly — so the source is internally consistent. Two of those classes have **no home in our model at all**: our Israel setup maps nominal 6.5t, 7.5t, 10t, 11t and 12t only.

WEIGHT CLASS, AT 30 JUNE 2026	REGISTERED	AVG AGE	MAPPED IN OUR MODEL?
6.5 – 7.5 t	8,610	9.4 yr	Yes — we show 6,101 (29% low)
7.6 – 10 t	2,485	6.2 yr	No class exists
10.1 – 12 t	2,697	5.9 yr	Partly — medium row 14% low
12.1 – 16 t	227	5.6 yr	Above everything we map
Total	**14,019**	—	**Model shows 10,760**

Do not multiply Israel by 1.25. That would hide the defect for one year and return next year. Rebuild on the government classes, add 7.6–10 t and 12.1–16 t, and add an age floor — the same fix the UK received in V15 and Israel never got. There are **1,680 vehicles first registered 1999–2010 still on the road**, 12% of the fleet, aged 16 to 27 years. Our Israel curve is at 5% survival by age 19 and zero by 20: we are scrapping vehicles the government says are registered.

Confirmed decision: government data outranks the shipment file. It is the primary source.

06 Two things the file asserts that the evidence denies

Medium-duty is plan fiction

Four medium-duty rows — Ireland, Portugal, Greece, Cyprus — are empty through 2025 and then grow purely on plan numbers. Portugal reaches 498 medium-duty vehicles by 2030 starting from nothing. The shipment register settles it: across **all 3,238 vehicles** shipped to Europe since 2020, every single one is a light N-series or an F-series. **Not one medium-duty unit exists.**

VEHICLES IN SHIPMENT REGISTER	MEDIUM-DUTY UNITS FOUND	PORTUGAL MD PLANNED BY 2030	RECOMMENDED TREATMENT
3,238	0	498	Plan-only
2020 – mid-2026, seven markets	across six years	from an empty history	outside Grand Total

Move these rows into a clearly labelled plan-only block, held outside the Grand Total until a first real registration appears. Germany needs the same treatment for a different reason: its 2019–2024 history was manufactured by running the 3% rule *backwards* from a single 2025 data point, so both its history and its forecast rest on the same wrong number, in a market with no registration data at all. Mark it indicative.

> **One thing the register exonerates.** The 2025 shipment trough is not missing data — it is the P700 model changeover, the largest product overhaul Isuzu has run in Europe in thirty years. The outgoing range winds down through 2024, 2025 troughs, the new range flows from 2026. The trough must not be used as a forecast baseline, and Ireland's step from 61 registrations to a plan of 216 looks materially less extreme against the pre-changeover average of about 89 a year. It is still a 2.4× step and still needs justifying — but against the right comparison.

07 GPS: why €/UIO misleads and capture does not

Two lenses are in circulation and they are not interchangeable. **Parts € per UIO** makes a distributor look rich or poor depending on how heavy its vehicle mix is — it is not comparable across markets. **GPS capture**, actual parts sales divided by target wallet, is comparable. The network sits at **51.1%** for CY2025 excluding MIDI. Use capture.

But capture is only comparable if the wallet is right, and today it is not. The target wallet depends on model group, and the car park file has no model split for these markets — the model column simply reads "LD" for every N-series vehicle. The mapper reads "LD" and returns the 7.5-tonne rate. **So a 3.5-tonne N35 Grafter is charged €739 of annual parts wallet instead of €296.**

Annual target wallet per vehicle. The grey bar is what a 3.5-tonne Grafter is charged today; the two right-hand bars are the candidate correct rates.

> **The N35 rate is dead configuration.** The targets file carries an N35 Grafter line at €296, but no code path can ever return it — and the branch that does look for "N35" routes to the €250 pickup rate instead. The configuration and the code disagree, and neither produces €296. Separately, the mapper's own documentation still quotes €1,120 and €1,344 — those are pre-margin figures; the live rates are €739 and €887. Anyone reading the code comment will quote a number 52% too high.

The distortion is concentrated in Portugal

How much this matters depends entirely on how many 3.5-tonne vehicles a market runs, and that varies enormously. Belgium has the highest Grafter share but almost no trucks, so it barely moves. **Portugal is the real exposure** — roughly two-thirds of its N-series shipments are 3.5 tonne, and its target wallet is potentially overstated by about a fifth, which means its GPS capture is understated by about a quarter.

MARKET	SHARE OF N-SERIES AT 3.5 T	EFFECT ON TARGET WALLET
Portugal	68.5%	Material — wallet potentially ~22% too high
Belgium	85.7%	Negligible — wallet is almost all pickups
Ireland	6.3%	Negligible
Germany, Malta, Cyprus, Greece	0%	No effect

Caveat that must travel with these figures. The 3.5-tonne shares are measured on what was *shipped* 2020–2026 and applied to the *whole* 2025 fleet. Older vehicles may carry a different mix, and the register does not reach before 2020. Treat this as a reliable indication of *size and direction*, not as a restatement of Portugal's GPS. **For Portugal specifically, do not restate from this figure** — Portugal has its own primary source. A measurement built from I-Motors' actual vehicle registrations puts the 3.5-tonne share of the truck fleet nearer **64%** rather than 68.5%, and that registration-based number is the one already used in the Portugal target work. The shipment share belongs here as network-wide evidence, not as Portugal's answer. And keep the two GPS families apart: the network lock of 51.1% and the Portugal meeting figure of 63.3% are different constructions — neither should silently overwrite the other.

08 What we are asking for

Three decisions, one immediate instruction, and a build order. Nothing here requires new data collection except where noted.

#	DECISION REQUIRED	RECOMMENDATION
1	Adopt one survival-curve method for the whole horizon 1990–2030 and delete the flat 3% rule from the forecast columns.	**Approve.** Leave UK CV rows 22 and 24 alone — they already use a proper curve and an age floor. UK LCV row 25 is in scope.
2	Quote **44,926** as IUK LCV CY2026 for FY27 GPS and Extended Target, replacing the +3.13% growth assumption with −6.0%.	**Locked 30 July 2026.** Already decided; this pack records it so the old number stops circulating.
3	Rebuild Israel on Ministry of Transport registrations as primary source, adding the two unmapped weight classes and an age floor.	**Confirmed.** Government data outranks the shipment file. Chase the underlying extract — the presentation is a picture of the data, not the data.
4	Medium-duty rows and Germany move to a labelled plan-only block, outside the Grand Total, until a real registration appears.	**Approve.** Zero medium-duty units in 3,238 shipped vehicles is not a rounding issue.
5	Decide the 3.5-tonne N35 Grafter wallet: €296 on its own line, or €250 with the pickups.	**Open — needs an owner.** The file says €296, the code does €250, and today the vehicle is charged €739. All three cannot stand.

Immediate, before any Kosha or action-plan figure is quoted. The MIDI filter on the live file is currently set to **"Include"**. Every headline total it produces right now carries MIDI Europe inside it — 95,395 vehicles in 2025, roughly 37% of the Grand Total. MIDI Europe is not an ISZE distributor. Set the filter to "Exclude MIDI" and re-read before quoting anything. This is a ship check, not a footnote.

Build order

STEP	ACTION	ACCEPTANCE TEST — HOW WE KNOW IT WORKED
0	Archive a dated copy of V19	Today the only copy of V19 that exists is the working file itself.
1	Israel rebuild on government classes	2026 reconciles to **14,019** class by class, with every exclusion written down.
2	Survival curve across 2026–2030, including UK LCV row 25	IUK LCV CY2026 = **44,926**. No discontinuity at the 2025/26 boundary. Backward-run lands on history within one unit.
3	Plan handling: level one-to-one, annual profile smoothed	Pickup parc in 2030 is **smaller** than 2025. Falling registrations cannot grow a fleet.
4	Flag Belgium, Cyprus, Malta, Greece as low confidence	No row grows faster than its registrations divided by its survival-curve length.
5	Correct the weight decode and the GPS N35 target CAN RUN IN PARALLEL	Re-run GPS; confirm no distributor breaks 100%. Portugal moves most.
6	Rewrite the method and source documentation	Every forecast number traces to a named file that actually exists on disk.

Explicitly out of scope for this release: the summary tables further down the overview sheet, stale and misaligned since roughly V12. They need their own rebuild, not a patch inside this one, and bundling them would put the whole release at risk.

What V20 delivers. A fleet model whose forecast uses the same method as its history; a pickup outlook that falls when registrations fall; an Israel number anchored to government registrations; plan rows that are honest about being plans; and a GPS wallet that reflects the vehicle actually sold. The historical car park — the part everyone relies on — is unaffected throughout.

Sources: the live ISZE Units-In-Operation overview workbook (V19, June 2026) read directly, cell by cell, including its own changelog and file metadata for the provenance of the June method change; the Japan shipment register of 3,238 individually identified vehicles, 2020 to mid-2026; Israeli Ministry of Transport registered-fleet figures via the distributor's July 2026 parts presentation; IMIT's November 2025 registration study; the ISZE mid-term sales plan FY2025–FY2030; and the GPS per-model target wallet configuration and its mapper. All V19 figures, the 3% scrap mechanism, the Ireland and Portugal shipment counts, the Israel gap, the 3.5-tonne market mix and the weight-decode error were independently reproduced from these files for this pack. Corrected forecast paths are computed as a constant-hazard equivalent (10.2% commercial vehicle, 12.3% pickup) to size the error; the V20 rebuild will apply the full cohort survival curve and will differ from these figures by a few per cent. Three inputs are reproduced as cited rather than independently re-derived, because they are not held in the files read here: the IMIT registration forecast, the Irish government registration counts on the right-hand side of the shipment comparison, and the Portugal target-wallet effect. The shipment side of that comparison, the sales-plan inputs and every V19 figure were verified directly. Israel weight-class figures carry the source's own caveat: one chart in the presentation is not reliably readable and the underlying data extract is still outstanding.
