ISZE ANALYTICS — METHOD NOTE

PRISM

Parts Revenue Intelligence & Sales Monitor

Every capture rate, every € gap, every GPS score ISZE reports back to a named file and a named script — not a spreadsheet someone remembers building six months ago. This is what PRISM is, how a number moves through it, and why that number is safe to put in front of Isuzu Motors Limited.

1 · Why one number needs three layers

A euro of parts revenue means nothing on its own — €500K sounds big for a 5,000-truck fleet and thin for a 50,000-truck one. PRISM never reports a raw figure without first anchoring it to the fleet. Everything below is denominated against the same foundation.

GPS and PMS are siblings, not a chain. Both divide sales against the same UIO denominator, but at different resolution — GPS is the wallet-level macro read across every part; PMS is the job-level micro read on the specific maintenance parts. Neither depends on the other, so a GPS swing in a market never explains a PMS swing there, and shouldn't be used to.

1

Fleet first, always

No sales figure is quoted without the surviving-parc denominator behind it. A distributor with a small fleet and strong € per truck can outrank one with ten times the sales.

2

GPS answers "how much"

€ per truck per year, traffic-lighted: above €150 is healthy, €50–150 is at risk, below €50 is critical. One number per distributor per year.

3

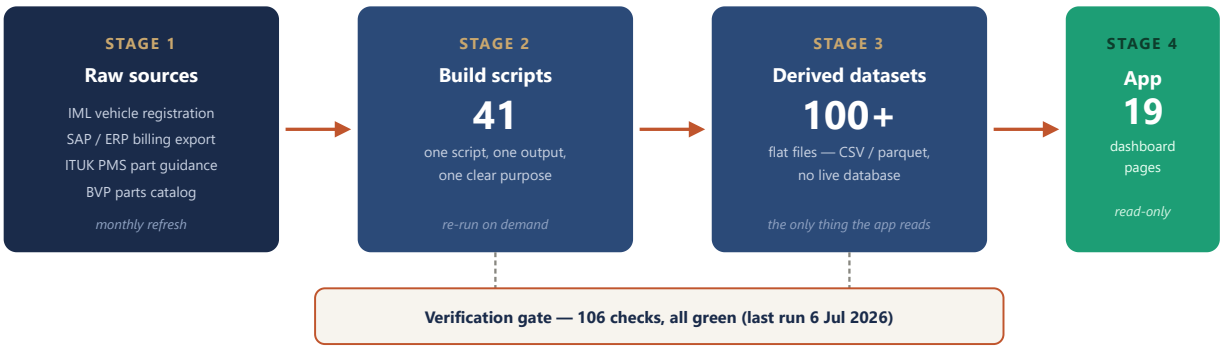

PMS answers "which job"

Capture rate on the specific service parts an Isuzu should be buying at a given interval — the number that tells you where a dealer visit is walking out the door to the aftermarket.

2 · How a number actually gets made

Nothing on a PRISM dashboard is typed in by hand, and nothing queries SAP live. A number travels through three fixed stages — each one a file on disk, each one re-runnable, each one inspectable after the fact.

The app never talks to SAP. It reads only Stage 3's flat files — which means a dashboard number is only ever as fresh as the last pipeline run, and that run is a deliberate, logged action, not a background query that can silently drift or fail.

3 · The insight PRISM exists to surface — across all 18 markets

Not a single-market story. Every distributor with usable fleet data, CY2025, both layers side by side: the macro wallet number (GPS, blue) against the job-level number that actually decides whether a service visit stays genuine (PMS wear-part capture, red).

MARKETS SCORED

18

of 22 — 4 have no usable UIO/GPS data yet

GPS MACRO READ

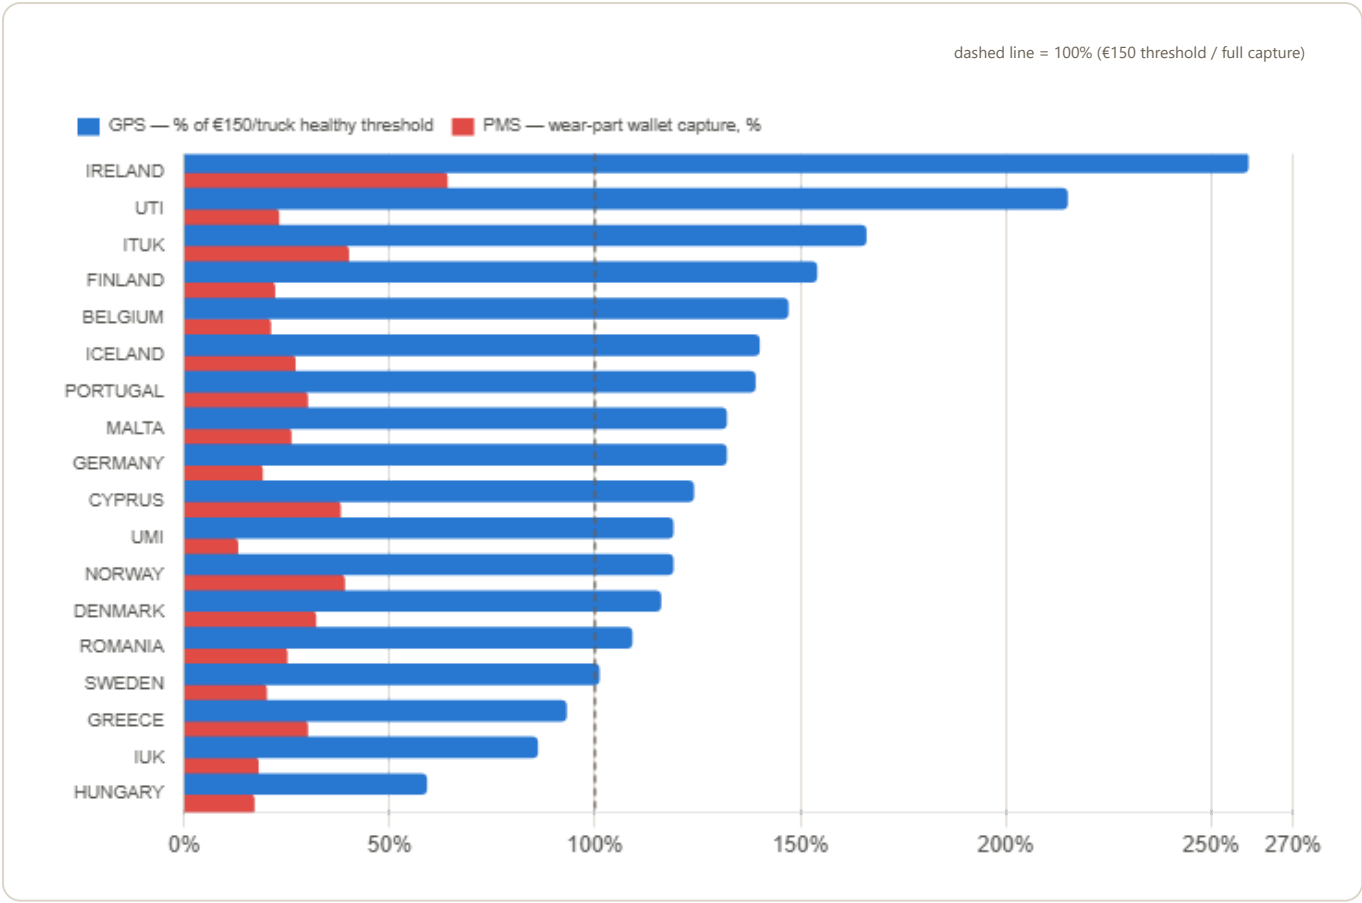

15 green, 3 amber

€/truck traffic light — almost every market looks healthy

PMS WALLET CAPTURE

13%–64%

not one market clears two-thirds of its wear-part wallet

The macro number and the job-level number tell different stories. Fifteen of eighteen markets sit GPS-green — comfortably above the €150/truck healthy line, some well over 200%. On the same fleet, in the same year, PMS wear-part capture — the % of expected oil filters, brake pads and clutch jobs actually sold genuine — never once reaches two-thirds, and the two rankings don't move together. A distributor can look entirely healthy on the wallet number while still losing the majority of specific service jobs to the aftermarket. That gap is exactly why PRISM keeps GPS and PMS as independent layers instead of collapsing them into one blended score — collapsing them would hide this.

A

Auditable

Every bar above traces to a named build script and raw source — no "someone remembers how this was calculated."

B

Reproducible

Re-run the same pipeline on the same inputs and you get the same output, byte for byte — not true of a live query against a moving ERP table.

C

Gated

106 automated checks must pass before a refreshed number reaches a dashboard or a deck — a fabricated or drifted figure fails loudly, not quietly.

4 · What "capture" actually counts

The capture numbers on the previous page are never genuine-only. Every PMS figure in PRISM adds two things together — and treats a third as the only real loss.

Aftermarket

Bosch, Febi, budget brands — the customer's money leaves ISZE entirely. This is the only segment PRISM treats as a loss.

Genuine

Full-price Isuzu part. Counted in capture.

BVP

Isuzu's own value line — still ISZE revenue, still counted in capture. A genuine sale that downtrades to BVP would otherwise often go to the aftermarket for €0.

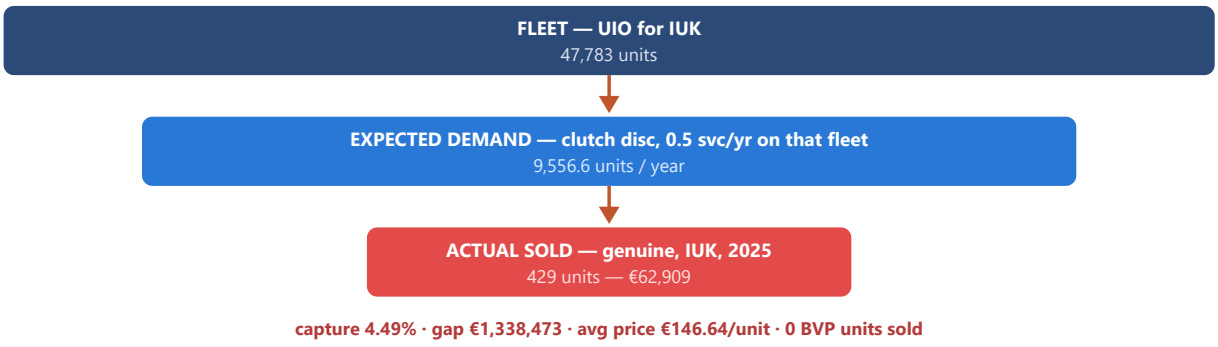

The network-wide split of what PRISM counts as "captured" on the PMS wear-part wallet, CY2025 — every euro of it stayed with ISZE:

A euro that moves from genuine to BVP is still an ISZE euro. PRISM's headline PMS metric is capture — genuine plus BVP together — never genuine share alone. Treating a rising BVP mix as "leakage to fix" would mean chasing a customer back toward genuine at full price when the honest alternative, in a low-capture category, is often losing them to the aftermarket entirely. Genuine/BVP mix is tracked as a margin-quality signal, not a loss.

5 · One number, start to finish

The abstract four-stage pipeline from page two, followed for one real cell: IUK, clutch discs, CY2025. Nothing below is illustrative — every figure is the actual pipeline output for this distributor and category.

capture 4.49% · gap €1,338,473 · avg price €146.64/unit · 0 BVP units sold

Where this number is built and where it lands. Stage 2 script `build_pms_opportunity_matrix.py` joins actual SAP sales to expected demand and writes this exact row to the Stage 3 dataset. From there it feeds the PMS dashboard page — and, this cycle, it's Action #1 in the Pricing Action Map: IUK clutch, €2.3M wallet, 4–6% capture across the family. Street pricing on the sample is not the blocker — genuine already prices at or below the aftermarket. The loss is availability, not price — a conclusion only visible once the number was traced this precisely.

6 · What PRISM admits it doesn't know yet

The gate on page three catches arithmetic drift. It does not resolve judgment calls — those are logged openly instead of quietly smoothed over.

Air-filter service interval — provisional

Expected air-filter demand uses a 0.5× interval factor (element changed roughly every second service) instead of every service. It roughly doubled measured air-filter capture network-wide the day it was applied. It is a labelled working assumption, not an IML-confirmed figure — every air-filter capture number carries that caveat until IML confirms the real ratio.

Credit notes / returns — a reversible judgment call

280 billing rows network-wide, 2023–2026 (€1,651,149), carry an explicit credit/return code on a positive-value line. PRISM now excludes them from revenue, parts base and PMS capture — a deliberate choice, not an ERP-confirmed netting rule. If SAP later confirms the code means something else, the exclusion reverts by narrowing one definition, and every downstream number recalculates from the same rule.

Known-wrong numbers don't get to quietly resurface. PRISM keeps a standing blacklist of figures that were once used and later proven wrong — including one fabricated competitive-share number that made it into a deck before being caught. Every entry on that list stays flagged permanently, specifically so a disproven number can't work its way back into a brief because someone half-remembered it from months ago.

7 · Where to look for what

Three questions cover almost everything PRISM is asked. Each one lives on a different level of the same hierarchy from page one.

"How big is the fleet, really?"	→	**UIO page** — surviving parc by distributor, model and registration year, sourced directly from IML.
"Are we capturing the parts wallet?"	→	**GPS page** — € spend per truck per year, traffic-lighted against the €150 / €50 healthy-to-critical bands.
"Are we winning the specific service jobs?"	→	**PMS page** — capture rate on the maintenance parts an Isuzu should be buying at its service interval, by distributor and model.
"Does this figure match what I saw last month?"	→	**FACTS.md** — the one authoritative source; if a number disagrees with it, the number is wrong until proven otherwise, not FACTS.md.

> **The practical rule.** Never quote a raw export, a half-remembered figure from a prior deck, or a screenshot as current truth. If it came out of PRISM's pipeline and passed the 106-check gate, it's safe to put in front of Isuzu Motors Limited. If it didn't, say so before it goes in a slide.

The point of PRISM isn't the dashboards — it's that every number behind them can survive being questioned.
